

7. Project Documentation Phase

Project Title

Script-Controlled ACL – Restrict Record Access Based on Field Value

Documentation Overview

The Project Documentation Phase involves recording the complete details of the project in a clear and organized manner. The documentation explains the purpose, configuration, implementation, testing, and final outcome of the Script-Controlled ACL.

Proper documentation helps users and developers understand how the access-control system works.

Project Description

The project uses a Script-Controlled Access Control List to restrict access to records based on a specific field value.

The ACL checks the selected field and evaluates the defined condition. Based on the result, the system either allows or restricts access to the record.

Configuration Details

The documentation includes the important configuration details of the ACL, such as:

- Target table
- Access operation
- Selected field
- Access condition
- ACL script
- User access requirements

These details help in understanding how the ACL has been configured.

Implementation Details

The implementation section describes the steps followed during development.

The main steps are:

1. Select the required table.
2. Identify the field used for access control.
3. Create the required ACL.
4. Configure the access condition.
5. Add the required script.
6. Save and activate the ACL.
7. Test the access behavior.
8. Testing Documentation

The testing results are recorded as part of the project documentation.

The main results include:

Condition	Result Matching field value	Access Allowed	Non-matching field value	Access Restricted
-----------	-----------------------------	----------------	--------------------------	-------------------

Screenshots of the ACL configuration and testing results can also be included in the final project report.

Security Documentation

The documentation explains how the ACL improves record-level security. It ensures that users cannot access records when the required field-value condition is not satisfied.

This provides an additional layer of protection for application data.

Result

The final result of the project is a working Script-Controlled ACL that dynamically controls record access.

The system checks the specified field value and makes an access decision based on the configured condition.

Conclusion

The Project Documentation Phase records the complete implementation and testing details of the Script-Controlled ACL. It provides a clear reference for understanding the project and its access-control mechanism. The completed documentation can be used during the final Project Demonstration Phase to explain the implementation and results.
